Sequences: Revision

**SKILLS
FOR LIFE**

SKILLS BOOTCAMPS

Department
for Education

Software Engineering Lecture Housekeeping

- The use of disrespectful language is prohibited in the questions, this is a supportive, learning environment for all - please engage accordingly.
(FBV: Mutual Respect.)
- No question is daft or silly - **ask them!**
- There are **Q&A sessions** midway and at the end of the session, should you wish to ask any follow-up questions. Moderators are going to be answering questions as the session progresses as well.
- If you have any questions outside of this lecture, or that are not answered during this lecture, please do submit these for upcoming Open Classes. You can submit these questions here: [Open Class Questions](#)

Software Engineering Lecture Housekeeping cont.

- For all **non-academic questions**, please submit a query: www.hyperiondev.com/support
- Report a **safeguarding** incident: www.hyperiondev.com/safeguardreporting
- We would love your **feedback** on lectures: [Feedback on Lectures](#)

Progression Criteria

✓ **Criterion 1: Initial Requirements**

- Complete 15 hours of Guided Learning Hours and the first four tasks within two weeks.

✓ **Criterion 2: Mid-Course Progress**

- Software Engineering: Finish 14 tasks by week 8.
- Data Science: Finish 13 tasks by week 8.

✓ **Criterion 3: Post-Course Progress**

- Complete all mandatory tasks by 24th March 2024.
- Record an Invitation to Interview within 4 weeks of course completion, or by 30th March 2024.
- Achieve 112 GLH by 24th March 2024.

✓ **Criterion 4: Employability**

- Record a Final Job Outcome within 12 weeks of graduation, or by 23rd September 2024.

Lecture Objectives

1. **String Fundamentals**
2. **Lists Fundamentals**
3. **List Comprehension**
4. **2D Lists**
5. **Fundamentals of Dictionaries**

What are Sequences?

- ★ A sequence is a collection of elements that are ordered and indexed, allowing for efficient access to individual elements by their position.
- ★ Sequences maintain the order in which elements are added and can contain duplicate values.

Strings

String Creation and Initialization

```
message = "This is a string"  
print(message)
```

Python String Methods

Input	Method	Output
"Hello World"	<code>.endswith("by")</code>	False
"Hello World"	<code>.startswith('Hello')</code>	True
"hello world"	<code>.capitalize()</code>	"Hello World"
"13/11/2021"	<code>.split("/")</code>	["13", "11", "2021"]
" Hello "	<code>.strip()</code>	"Hello"
"Hello A"	<code>.replace("A","B")</code>	"Hello B"
"hello world"	<code>.count("o")</code>	2
"Hello World"	<code>.find("o")</code>	4
"123456"	<code>.isnumeric()</code>	True
"HELLO"	<code>.lower()</code>	"hello"
"hello"	<code>.upper()</code>	"HELLO"

Strings Are Immutable

- When an object is immutable it means the object cannot be changed.
- When we apply methods to a string that appear to make changes, they are actually creating and returning new string objects.
- This means we have to store the changes we make in a variable to be reused.

String Indexing

Python

0 1 2 3 4 5

-6 -5 -4 -3 -2 -1

String Slicing

`str1[1:3] = AC`

`str1[-3:-1] = AC`

String Concatenation & Formatting

String Concatenate

"Hello" + "World" = " HelloWorld "

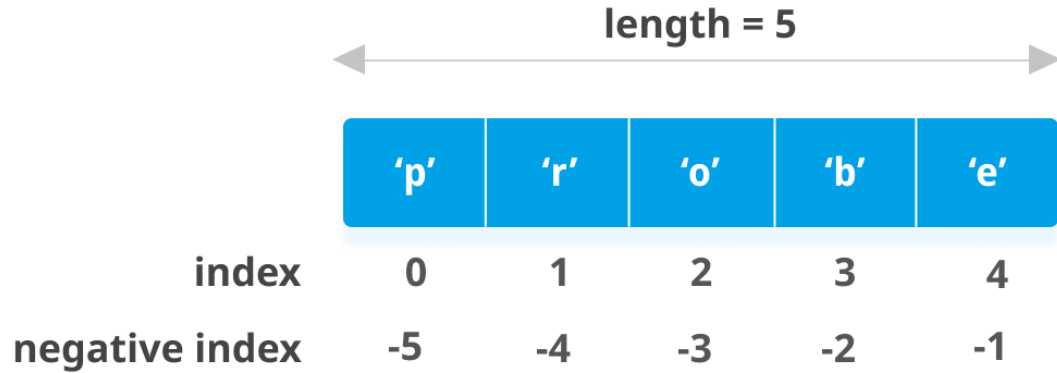

String 1 String 2 Result

f-strings and format() function

```
location = 'World'  
print(f"Hello, {location}!")
```

Lists

Lists

- ★ A list is a data type that allows us to store multiple values of any type together and a list can contain duplications.
- ★ We can access individual values using indexing and multiple values using slicing.
- ★ We can iterate over lists using a for loop.

-6	-5	-4	-3	-2	-1
A	B	C	D	X	y
0	1	2	3	4	5

Lists ...

- ★ Lists are mutable.
- ★ This means the values inside a list can be changed and unlike a string won't return a new list when changes have been made.
- ★ We can apply methods to our lists without having to restore them inside our variables.

Lists ...

- ★ To create a list we can surround comma separated values with square brackets. []
- ★ E.g. `my_list = [value1, value2, value3]`
- ★ Adding Elements: `append()`, `insert()`
- ★ Removing Elements: `remove()`, `pop()` and `'del'`
- ★ Manipulating elements: sorting, reversing and slicing

List Example

```
num_list = [1,2,3,4,5]  
new_num_list = num_list  
  
new_num_list[2] = 200  
print(num_list)
```

```
[1, 2, 200, 4, 5]
```

List Example

```
num_list = [1,2,3,4,5]  
new_num_list = num_list.copy()  
  
new_num_list[2] = 200  
print(num_list)
```

[1, 2, 3, 4, 5]

List Comprehension

LIST COMPREHENSION

Output

Collection

Condition

↑ ↑ ↑
`[x+1 for x in range(5) if x%2 == 0]`

`Do this for this collection In this situation`

List Comprehension

- ★ List comprehension is a condensed method for creating lists in Python. In comparison to conventional for-loops, it offers a more condensed syntax for creating lists.

List Comprehension:

Basic Structure

```
new_list = [expression for item in iterable]
```

Squaring numbers from 0 to 9

```
squares = [x**2 for x in range(10)]
```

Result: [0, 1, 4, 9, 16, 25, 36, 49, 64, 81]

List Comprehension ...

```
List Comprehension:  
# Basic Structure  
new_list = [expression for item in iterable]  
  
# Squaring numbers from 0 to 9  
squares = [x**2 for x in range(10)]  
# Result: [0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

- ★ **Expression:** The expression to be evaluated and included in the new list.
- ★ **Item:** The variable representing an element in the iterable (e.g., a range, list, string).
- ★ **Iterable:** The source of data to iterate over.

Benefits & Precautions

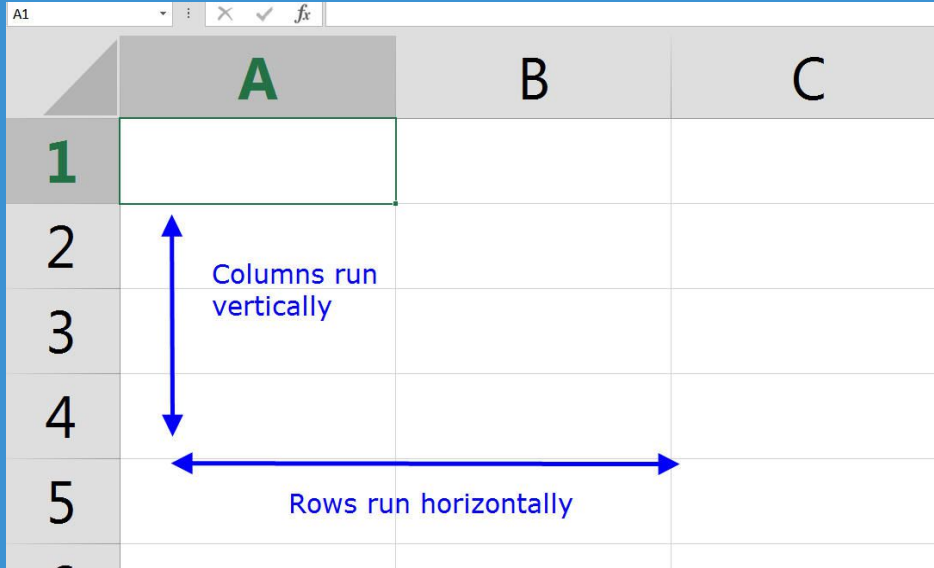

★ Benefits:

- **Conciseness:** Achieve the same result with less code.
- **Readability:** Express your intent more clearly and compactly.
- **Efficiency:** List comprehensions are often faster than equivalent for-loops.

★ Considerations:

- **Avoid Complexity:** While list comprehensions are powerful, avoid making them overly complex for the sake of readability.
- **Conditional Expressions:** Can be used for conditional inclusion.
ie. `value_if_true if condition else value_if_false`

2D Lists

A screenshot of an Excel spreadsheet illustrating a 2D list structure. The spreadsheet has columns labeled A, B, and C, and rows labeled 1 through 5. The cell A1 is highlighted. A blue double-headed arrow points vertically from row 1 to row 5, with the text "Columns run vertically" next to it. Another blue double-headed arrow points horizontally from column A to column C, with the text "Rows run horizontally" below it.

	A	B	C
1			
2			
3			
4			
5			

2D List

- ★ A list within a list.
- ★ Outer List (1 Dimension) + Inner List (1 Dimension) = 2D

Rows and Columns

- ★ Elements are essentially accessed using rows and column indices.

```
two_d = [  
    [1, 2, 3],  
    [4, 5, 6],  
    [7, 8, 9]  
]
```

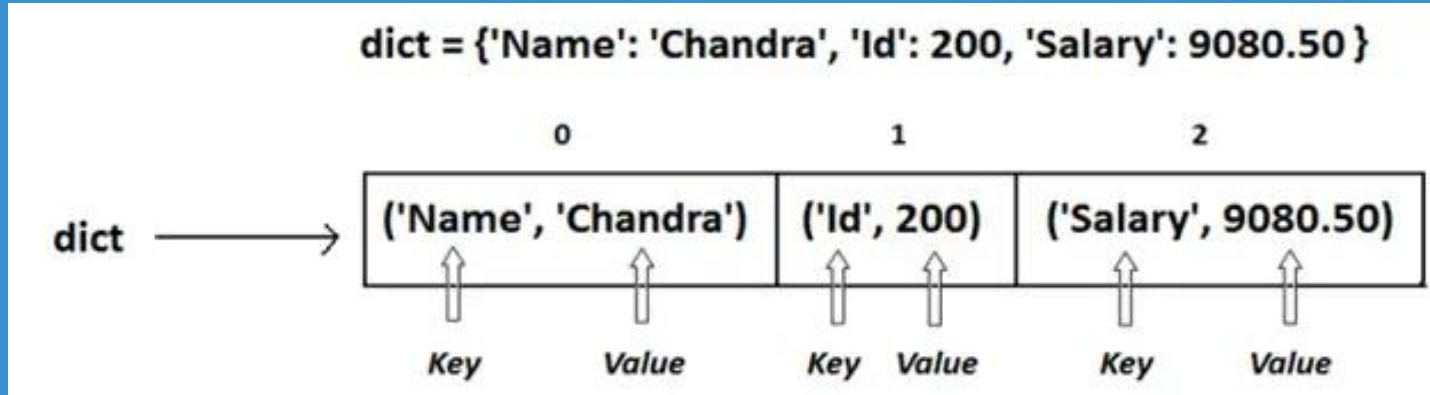

Traversing the 2D

- ★ Nested Loops (iterate through rows and columns)
- ★ List comprehension

A 3x3 grid illustrating 2D traversal. The grid is composed of colored squares, each containing a coordinate pair (row, column). The rows are indexed 0, 1, and 2 from top to bottom. The columns are indexed 0, 1, and 2 from left to right. A yellow box labeled 'Column Index' has an arrow pointing to the column headers. A yellow box labeled 'Row Index' has an arrow pointing to the row headers.

	0	1	2
0	(0,0)	(0,1)	(0,2)
1	(1,0)	(1,1)	(1,2)
2	(2,0)	(2,1)	(2,2)

Dictionaries

Dictionaries

- ★ In Python, dictionaries function like the dictionaries we commonly use in English class, such as those from Oxford.
- ★ Python dictionaries are similar to a list, however each item has two parts, a key and a value.
- ★ To draw a parallel, consider an English dictionary where the key represents a word, and the associated value is its definition.

Dictionary Example

```
# Dictionary Example

my_dictionary = {
    "name": "Terry",
    "age": 24,
    "is_funny": False
}
```

- ❖ Dictionaries are enclosed in curly brackets; key value pairs are separated by colon and each pair is separated by a comma.
- ❖ On the left is the key, on the right is the value.

Dictionary Function

- ❖ The dict() function in Python is a versatile way to create dictionaries or cast to dictionary data type.
- ❖ Create dictionaries through assigning values to keys by passing in keys and values separated by an = sign.

```
# Creating a dictionary with direct key-value pairs
my_dict = dict(name="Kitty", age=25, city="Belarus")
print(my_dict)
# Output: {'name': 'Kitty', 'age': 25, 'city': 'Belarus'}
```

Dictionary Update

- ❖ To append or add elements to a dictionary in Python, you can use the `update()` method or simply use the square bracket notation.

```
my_dict = dict(name="Kitty", age=25, city="Belarus")
# Adding or updating a key-value pair
my_dict.update({'breed': 'Shorthair'})
print(my_dict)
# Output: {'name': 'Kitty', 'age': 25, 'city': 'Belarus', 'breed': 'Shorthair'}
```

Dictionary Access

- ❖ To access a value in a dictionary, we simply call the key and Python will return the value paired with the provided key.
- ❖ Similar to indexing, however we provide a key name instead of an index number.

```
my_dict = dict(name="Kitty", age=25, city="Belarus")  
name = my_dict["name"]  
# Output: 'Kitty'
```

Dictionary Operations

❖ Key-Value Pairs

- `items()` - *for key, value in my_dict.items()*

❖ Fetching

- `get()` - *name = my_dict.get('name')*

❖ Updating

- `update()` - *update_dict = {'age': 29, 'salary': 60000}*
- *my_dict.update(update_dict)*

❖ Deleting

- `pop()` - *age = my_dict.pop('age', 'Not Specified')*
